Steps to clean the data :
1. Remove misspelt words if any by using appropriate tools :

    We can use the drop () method in pandas to go about this, and drop the elements with undesirable values.

    In case of dropping a column, axis=1 should be passed as a parameter to the drop() method

    We do this because misspelt words will make our output go wrong

2. Remove unwanted symbols to keep only important words :

    Use the drop() method here as well to remove the symbols that we consider undesirable(noise)

    We do this because symbols will make our output go wrong

3. Remove NaN values if any present for some reason :

    We use the dropna() method for this. NaN values are noise in data
